Abstract:

Daily body and Hematological parameters were recorded following an attempt to manage clinical compound fractures of 18 healthy Kano Brown goats using Sherman's compression plates via internal reduction. The hematological parameters before, during and after surgery were determined by full blood count. The results showed that inflammatory cells such as nuetrophils, esinophils and lymphocytes were at their peak when the implants were in the body of the animals. There was significant increase ($P<0.05$) in total leukocyte counts a week after surgery. This increase could be attributed to the presence of bone plates. Other parameters such as body temperature, pulse rate, respiratory rate, were recorded for 160days. Body temperature, respiratory and pulse rates dropped to normal physiologic rates after implants were removed and healing was complete.

It was concluded that implants plays important role in stimulating leukocytosis.

Key Words: Sherman's bone plates, hematological parameters, body temperatures.

Introduction

Body and hematological changes in relationship to foreign objects/metals in the body as it relates to fracture is a product of inflammatory process during healing. The haemogram is a mirror image of the happenings in the body as it particularly guides and directs clinicians towards the health status of the body (Encarta, 2004). Cells such as; red blood cells, lymphocytes, monocytes, segmented nuetrophils, esinophils and basophils are important in wound healing. According to McRae (1981) fracture healing as been divided into three phases; Inflammatory, reparative and re-modeling phases.

The inflammatory phase is further divided into two sub phases; (a) formation and organization of fracture hematoma (b) invasion by inflammatory cells. It is believed that fracture hematoma is formed as soon as the bone breaks (Muller et al., 1979). Its source is ruptured blood vessel of the periostium, bone cortex, bone marrow and the surrounding soft tissues. The ends of the ruptured vessels soon cloth with little bleeding into the fracture site within 24hours (Steindler, 1985). The ends of the fractured bone, robbed of their blood supply, die off (avascular necrosis). This sub phase occurs in the first two days following fracture.

As reported by Hamble (1997), fracture hematoma begins to organize within a few hours. After this, the fracture site in invaded by inflammatory cells, notably multinuclear phagocytes and monocytes which set off to phagocytose necrotic and other non-necrotic debris including implants as previously observed by Hamble (1997). This process of phagocytosis continues for days or weeks depending on the amount of tissue to be removed. It is believed that this sub phase occupies mainly the 2^{nd} and 5^{th} post fracture day. The haemogram picture during the period coincided with an increase in level of inflammatory cells in circulation and a rise in body temperature (Mckibbin, 1978).

Material and Methods

This study took place in the Faculty of Veterinary Medicine, Ahmadu Bello University Zaria, North West of Nigeria.

Eighteen clinical cases of fracture of the tibial bone were used for this study. Animal were divided into 2 groups; A and B by simple random sampling technique. Group A had their fracture immobilized with bone pates without the use of bone cement while Group B were the study group had their fractures immobilized with bone plates with the use of bone cement.

The experimental animals were allowed a 24hours acclimatization before the surgery commenced. Vital parameters, such as body temperature, body weight, pulse rate, respiratory rate, age and status of the animal were taken. Blood was taken from all animals to establish the base line haemogram prior to surgery.

Two millimeters of blood were obtained from each goat through the jugular vein using a 21G $1^1/2$ needle (Discard IT®, Beton Dickinson, England). Sample was placed in a bottle containing 1mg of ethylene diamine tetra acetic acid (EDTA), and divided into two, properly labeled bottles and sent to the protozoology and haematology laboratory of Faculty of Veterinary Medicine, Ahmadu Bello University Zaria for analysis.

Blood sample were analyzed for packed cell volume (PCV) total leukocyte count (WBC), differential WBC counts as well as total plasma protein using an automated analyzer.

Automated hematology counters; automated machines have at least two channels for cell counting. In one channel red blood cells and platelets are analyzed, and in the other, white blood cells are analyzed. Extra channels are used for the differentials cell counting and reticulocyte counting. There are basically two methods for cell counting and sizing which are electrical impendence and light scattering. Although automated instruments are sophisticated, they cannot recognize all the significant abnormalities that can be recognized by the human eye. Therefore they are designed to produce accurate and precise blood counts on specimens which are either normal, or show only numerical abnormalities and to alert the operator when the specimen has unusual measurement or which would required a blood film review (Health, 2012).

Post surgical haemogram were also obtained at 3weeks and 16weeks (After implants use removed) after surgery. Rectal temperatures were recorded for 160days using digital thermometers pre, during and post surgery. Respiratory and pulse rates were also recorded pre, during and post surgery to 160days.

Post operative radiographs were taken at 0, 2(Figure 1), 4(Figure 2), 8, 12(Figure 3) and 16weeks to evaluate the extent of healing. After healing, a second surgery was carried out to harvest the implants (Figure 4, 5, 6 shows tibia bone 4 weeks after bone plates were harvested). Haemogram picture before surgery, one week post surgery and one week after the implant was removed were properly recorded.

Surgical procedure

The surgery was carried out via the bone plating technique as described by Piematti and Greely (1986).

Statistical analysis

Statistical analysis using two tailed student test was used to compare the mean values between and within groups and was found to be significant ($P<0.05$)

Results and Discussion

Packed cell volume (PCV) pre -surgery dropped from 28.5%, 25.5% during surgery to 27.1% post-surgery with a mean PCV of 26.9% for group A goats, white blood cells (WBC) was 8.2% before surgery, rose to10.1% and later dropped to 8.0% post surgery with a mean wbc 8.7%.Total protein before surgery was 5.6g/dl, during surgery 3.9g/dl and post surgery 4.6g/dl (Table 1).

For group B goats that were treated with bone cement as the study group, PCV pre-surgery was 29.5%, 25.5% during surgery, and 27.7% post- surgery, with a mean pcv of 27.4%. White blood cells pre-surgery was 8.3%, during surgery 11.6%, and post surgery 9.3%, with a mean WBC of 9.3%. Total protein before surgery was 5.1g/dl, during surgery 4.1g/dl and post surgery 4.6g/dl (Table 2).

Mean body temperature, pulse rate and respiratory rates for both group A and group B were; Temperature pre – surgery 38.7 degree Celsius, during surgery, 39.4 degree Celsius and post surgery 38.1 degree Celsius. While pulse rates were 75.1 beats /minute, 75.6 beats/minute, and 75.4 beats/minute pre, during and post surgery. Respiratory rates 29.8 cycle/minute, 30.7cycle/minute pre, during and post surgery.

Radiographic evaluations of figure 1, figure 2 and figure 3 indicate perfect alignment and commencement of callus formation with evidence of healing. Figures 4, 5, and 6 shows complete bone healing 4 weeks after implants were harvested with evidence of bone remodeling in progress.

Table 1: Mean hematological parameters in Kano Brown Goats with tibial fractures treated without Bone cement (Group A; 9 animals aged between 6-11months).

Group A

Blood parameter	PCVS (%)	WBC (%)	N (%)	L (%)	E (%)	M (%)	BAS	Total protein (g/dl)
Pre surgery	28.5	8.2	37.5	51.8	1.1	0.7	0	5.6
During Surgery	25.5	10.1	26.4	60.3	1.6	0.5	0	3.9
Post surgery	27.1	8.0	27.4	56.1	1.5	0.6	0	4.6
Mean	26.9	8.7	30.4	56.0	1.4	0.6	0	4.7
SD	±0.3	±0.2	±0.4	±0.4	±0.1	±0.1		±0.15

Key
Pcv - packed cell volume
WBC – White blood cell
N – Nuetrophils
L – Lymphocytes
E – eosinophils
M – Monocytes
g/dl - Gram per litre
SD – Standard deviation
BAS – Baseophils

Table 2. Mean hematological parameters in Kano Brown Goats with tibial fracture and bone cement application (Group B; 9 animals aged 15-20 months).

	PCV (%)	WBC ($*10^5/2$)	N (%)	L (%)	E (%)	M (%)	BAS	Total protein (g/dl)
Pre surgery	29.5	8.3	37.5	55.7	1.3	1.0	0	5.1
During Surgery	25.3	11.6	31.0	71.4	2.0	0.7	0	4.1
Post surgery	27.7	8.1	31.2	53.2	1.1	0.6	0	4.6
Mean	27.4	9.3	33.9	60.1	1.4	0.7	0	4.6
SD	±0.3	±0.2	±0.4	±0.4	±0.1	±0.1		±0.15

Key
Pcv - packed cell volume
WBC – White blood cell
N – Nuetrophils
L – Lymphocytes
E – eosinophis
M – Monocytes
g/dl - Gram per deciliter

Table 3: Mean body temperature, pulse rate and respiratory rate changes in Kano brown goat treated with or without bone cement.

	Temperature T^0c	Pulse Rate B/m	Respiratory Rate c/m
Pre surgery	36.7	75.1	29.8
During Surgery	39.4	75.6	30.7
Post surgery	38.3	75.4	30.5
Overall mean	38.1	75.7	30.3

Discussion

The significant increase ($P<0.05$) in total leucocytes count weeks after artificially creating the fractures could be attributed to the presence of bone plates. This feature occurred in both groups of goats, suggesting the role of the implant in stimulating leukocytosis response similar to the observation of mikibbin (1987). The leukocytosis response disappeared as the implants were removed one week after surgery in all the animals used for study. The PCV values also dropped one week post operatively for both groups. For example the mean PCV before surgery was 29.5 ± 0.5%, this dropped to 25.3 ± 03% one week after surgery, and subsequently rose to 27.1 ± 0.3% one week after the implant were harvested. The initial decrease in PCV level immediately after the surgery could be attributed to blood loss during the surgical procedure. The hematopoietic activity probably picked up as the normal physiologic activity was restored. The rise in total protein post surgery for both groups indicate post surgery recovery as the animals appetite improved considerably as healing progressed.

Mean values recorded during surgery indicate a mean temperature of 39.4±0.5 degree Celsius, pulse rate 75.6±0.3 beats/minute and respiratory rate of 30.7±0.8cycles/minute ,these were the values when the implants were in the animal, these values dropped to normal physiologic level when the implants were removed. From literature and in this study, the rise in temperature at the time the implant was in the animal coincided with the period when inflammatory cells were at their peak as indicated by the haemogram of this study. According to Zaheed et al., (2011), the invitro study they carried out on temperature change along dental implant supports the hypothesis that body temperature rises with presence of implants.

After the implants were removed body temperature reverted back to normal probably because the implant being an exogenous material had initiated a marked inflammatory response.

Statistical analysis using two tailed student was used to compare the mean values between and within groups and was found to be significant ($P<0.05$).

Conclusion

The body and hematological parameters recorded were at its peak when the implants were in the animal, this could be concluded to mean that exogenous materials like bone plates can cause leukocytosis, and rise in other body parameters like temperature, pulse and respiratory rates.

Acknowledgement

We seriously appreciate the following surgeons of the Department of Veterinary Surgery and Radiology, Ahmadu Bello University, Zaria; Dr's Bala Usman and Augustine Andrew. The entire staffs of department are also acknowledged. Finally we are grateful to Professor Oladele Sunday blessing of Department of Veterinary Pathology, Faculty of Veterinary Medicine, Ahmadu Bello University, Zaria for reading and editing this manuscript.
